For the limit \( q \to q^{-1} \) we get
\[
\{n, m\} \equiv \lim_{q \to 1} [n, m]_q = \lim_{q \to 1} [n, m]_{q^{-1}} = \frac{1}{2}(n+1)(m+1)(n+m+2) = \dim \Gamma_{n,m},
\]
\[
\{n-1, n-1\} = n^3 = \dim \Gamma_{n-1,n-1},
\]
\[
\{n-1, 0\} = \{0, n-1\} = \frac{n(n+1)}{2} = \dim \Gamma_{n-1,0}
\]
For \( p \to 1 \) the \((q,p)\)-numbers \([r]_{q,p}\) turn into the Jackson \(q\)-numbers \([r]_q \equiv (1 - q^n)/(1 - q)\). We prove that
\[
[n, m]_{q,1} = q^{-(n+m)} \frac{[n+m+2]_q [n+1]_q [m+1]_q}{[2]_q},
\]
\[
[n, m]_{q,1} = q^{-2n} \frac{[n+1]^2_q [2(n+1)]_q}{[2]_q},
\]
\[
[n-1, 0]_{q,1} = q^{-n} \frac{[n]_q [n+1]_q}{[2]_q}.
\]

Some properties of generalized hypergeometric Appell polynomials

Leonid Bedratyuk, Natalia Luno

In [1], P.Appell presented the sequence of polynomials \( \{A_n(x)\} \), \( n = 0, 1, 2, \ldots \) which satisfies the following relation
\[
A'_n(x) = nA_{n-1}(x),
\]
and possesses the exponential generating function
\[
A(t)e^t = \sum_{n=0}^{\infty} A_n(x) \frac{t^n}{n!},
\]
where \( A(t) \) is a formal power series
\[
A(t) = a_0 + a_1 t + a_2 \frac{t^2}{2!} + \cdots + a_n \frac{t^n}{n!} + \cdots, a_0 \neq 0.
\]

The Appell type polynomials appear at the different areas of mathematics, namely, at special functions, general algebra, combinatorics and number theory. Recently, the Appell type
polynomials are of big interest. New approaches based on the determinant method and Pascal matrix method are applied (see, e.g., [2]–[3]).

Monomials $x^n$, Bernoulli polynomials, Euler polynomials and Hermite polynomials are the examples of the Appell type polynomials ([4]).

**DEFINITION.** Let us

$$\Delta(k, -n) = \frac{n}{k}, -\frac{n - 1}{k}, \ldots, -\frac{n - k + 1}{k}, \quad k, n \in \mathbb{Z}. $$

Then polynomials $A_n^{(k)}(m, x)$, $n = 0, 1, 2, \ldots$ where

$$A_n^{(k)}(x) = x^k N_{m+n} \left[ \Delta(k, -n), \alpha_1, \alpha_2, \ldots, \alpha_p; \beta_1, \beta_2, \ldots, \beta_q \mid \frac{m}{x^k} \right],$$

and $m, k \in \mathbb{N}_0$, $\alpha_1, \alpha_2, \ldots, \alpha_p, \beta_1, \beta_2, \ldots, \beta_p$ are the arbitrary number sets, we call generalized hypergeometric Appell polynomials.

In the case when $p = 0, q = 0, k := m, h := \frac{(-1)^k}{k^k}$ the generalized hypergeometric Appell polynomials $A_n^{(k)}(p, q; x)$ became the Gould-Hoppers polynomials [5], and with $p = 0, q = 0$ and $k = 2$ they are the well-known Hermite polynomials.

**Theorem 1.** Generalized hypergeometric Appell polynomials $A_n^{(k)}(m, x)$ are the Appell type polynomials.

**Proof.** To prove it one should replace $t \mapsto xt, \quad x \mapsto \frac{m}{x^k}$, in problem 26, p.173 [6], then the function $A(t)$ takes a form

$$A(t) = p F_q \left[ a_1, a_2, \ldots, a_p; b_1, b_2, \ldots, b_q \mid (-1)^k \frac{t^k}{k^k} \right].$$

□

Using the derivative properties of the composition of functions and the hypergeometric function we obtain

**Theorem 2.** The following identity holds

$$nx^{k-1} p F_q \left[ a_1, a_2, \ldots, a_p; b_1, b_2, \ldots, b_q \mid \frac{m}{x^k} \right] = $$

$$= km \frac{a_1 a_2 \ldots a_p}{b_1 b_2 \ldots b_q} \Delta_1(k, -n) p F_q \left[ a_1 + 1, a_2 + 1, \ldots, a_p + 1, \Delta(k, -n) + 1; b_1 + 1, b_2 + 1, \ldots, b_q + 1 \mid \frac{m}{x^k} \right] + $$

$$+ nx^k p F_q \left[ a_1, a_2, \ldots, a_p; b_1, b_2, \ldots, b_q \mid \Delta(k, -n + 1) \frac{m}{x^k} \right],$$

where

$$\Delta_1(k, -n) = \left(-\frac{n}{k}\right) \cdot \left(-\frac{n - 1}{k}\right) \cdots \left(-\frac{n - k + 1}{k}\right).$$

Further on, the generalized hypergeometric Appell polynomials possess the convolution type property.

**Theorem 3.**

$$\sum_{i=0}^n (-1)^i \binom{n}{i} A_i^{(k)}(m, 0) A_{n-i}^{(k)}(m, 0) = 2^n A_n^{(k)}(m, 0).$$

**Proof.** The proof is based on the method proposed in [7]. □

Tensor products of indecomposable integral matrix representations of the symmetric group of third degree

Diana Biletska, Ihor Shapochka

Let $S_3$ be the symmetric group of third degree with generators $a$, $b$ and relations: $a^2 = b^3 = e$, $ba = ab^2$, where $e$ is the identity of $S_3$. The result, which we have obtained, is based on the classification of all non-equivalent indecomposable integral matrix representations of the group $S_3$, obtained by L. A. Nazarova and A. V. Roiter [1]. The following representations of the group $S_3$ over the ring $\mathbb{Z}$ of rational integers presents all indecomposable integral pairwise
